StockTrader: Comparative Analysis Report

Momentum Trader vs. Value Contrarian — Multi-Agent Stock Analysis

*(Includes a third strategy — **Volatility Averse** — see §8.)*

1. Strategy Selection and Rationale

This project compares two strategies with fundamentally incompatible philosophies: the **Momentum Trader** (trend-following) and the **Value Contrarian** (mean-reversion).

The Momentum Trader believes that "the trend is your friend" — stocks that are rising tend to keep rising, and stocks that are falling tend to keep falling. It prioritizes price position relative to 20-day and 50-day moving averages, volume trend confirmation, positive-to-negative day ratios, and RSI as a momentum gauge. It explicitly ignores how far a stock is from its 52-week high, past drawdowns, and volatility. Its personality is aggressive and action-oriented, biased toward BUY and SELL over HOLD.

The Value Contrarian believes that "markets overreact — buy fear, sell greed." It prioritizes distance from 52-week extremes, RSI as an overbought/oversold indicator, drawdown magnitude, and volatility as a signal of emotional trading. It explicitly ignores moving average crossovers, volume trends, and short-term win/loss ratios. Its personality is patient and skeptical, biased toward HOLD over action.

As a **third strategy agent**, I added **Volatility Averse**: it prioritizes **path risk** — standard deviation of daily returns (30d/90d), **ATR** as a percent of price, worst single-day drop over 90 days, and max drawdown — and de-emphasizes trend vs. contrarian "story" framing. It runs in parallel with the other two on the same market data.

This pairing was chosen because the two strategies apply opposing interpretive frameworks to identical data. A stock trading above both moving averages with strong volume (Momentum's ideal BUY signal) could simultaneously be near its 52-week high with an elevated RSI (Contrarian's ideal SELL signal). The expected disagreement is structural, not random — it emerges from the incompatibility of their data hierarchies. I expected sharp disagreement on momentum-driven stocks (NVDA, TSLA) and potential convergence on stocks in neutral or clearly oversold territory (JNJ, INTC). I added **GME** (meme / retail-driven volatility) and **JPM** (large bank, rate–credit narrative) to stress-test the same prompts on non-tech regimes. **Actual** agreement and disagreement by ticker depend on the snapshot date; results below follow the saved JSON run (**2026-04-12**).

2. System Architecture

The system uses a parallel fan-out pipeline with four components orchestrated in plain Python with asyncio:

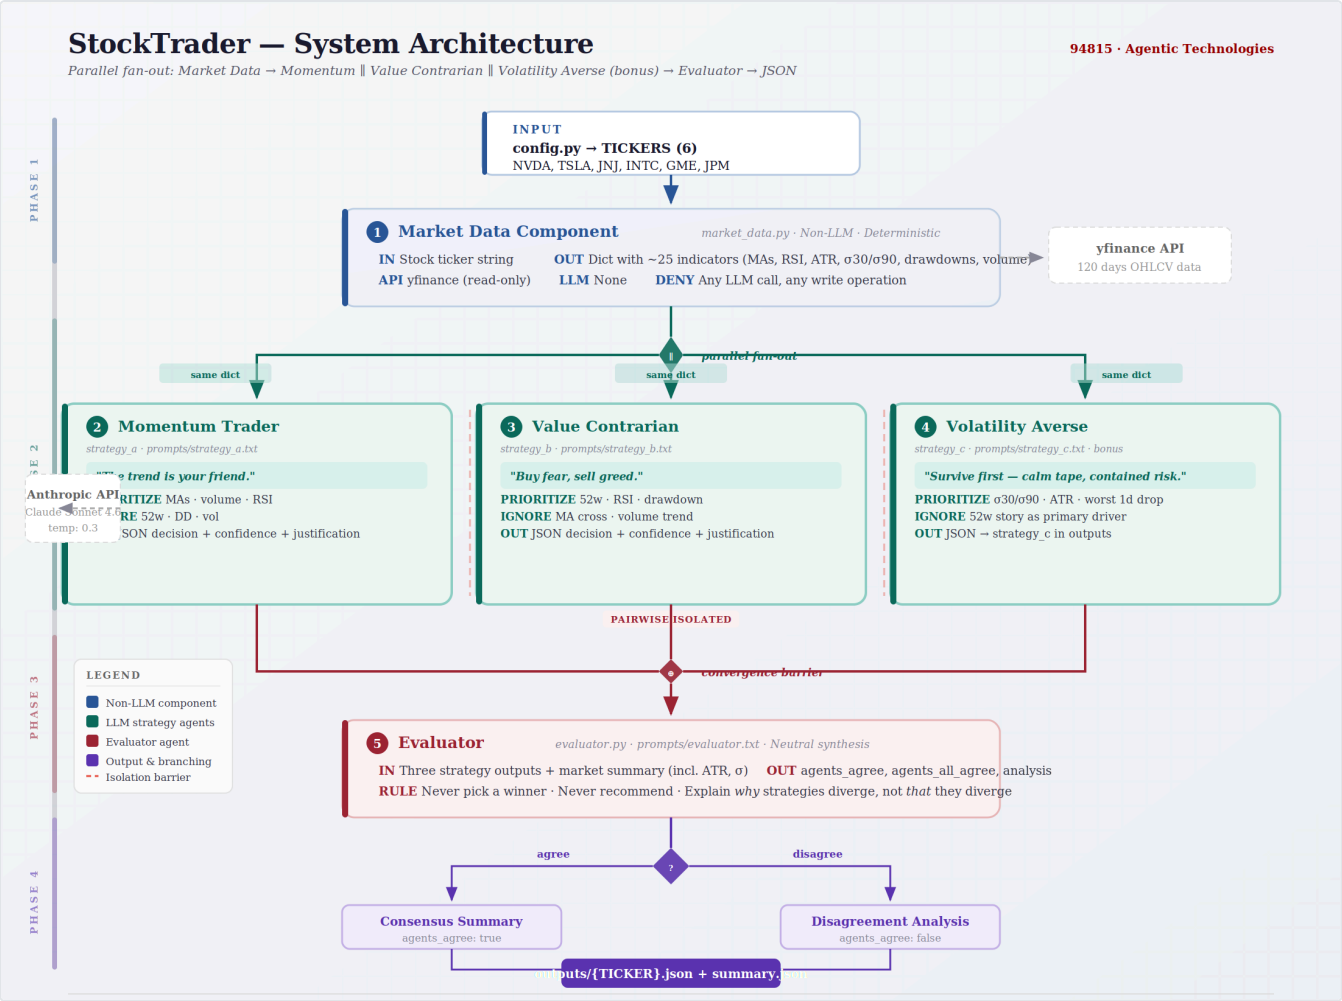

Figure 1: StockTrader system architecture — parallel fan-out with convergence barrier

Figure 1: StockTrader system architecture — parallel fan-out with convergence barrier.

The pipeline executes in four phases per stock:

Phase 1 — Data: The Market Data Component (non-LLM, deterministic) fetches 120 calendar days of OHLCV data from yfinance and computes derived indicators including moving averages, RSI, **30d/90d volatility** (std dev of daily returns), **14-day ATR** (and ATR % of price), worst single-day drop (90d), drawdowns, and volume trends. This component makes zero LLM calls.

Phase 2 — Analysis: Three strategy agents receive the **identical** market data dictionary (each with a strategy-specific user prompt). They execute concurrently via `asyncio.gather`. No agent sees another's output before producing its own — isolation is enforced by the orchestrator. All use Anthropic's Claude Sonnet (`claude-sonnet-4-6` via the Messages API) at temperature 0.3.

Phase 3 — Evaluation: Momentum vs. Contrarian agreement is computed first (`agents_agree`). **All-three** agreement is computed separately (`agents_all_agree`). The Evaluator receives **all three** strategy outputs plus a market summary (including volatility metrics) and is prompted for a **three-way** synthesis — unanimous, 2–1 splits, or three distinct decisions — **without** picking a "winning" strategy.

Phase 4 — Output: Results are assembled into structured JSON per stock (`strategy_a`, `strategy_b`, `strategy_c`, `evaluator`, `three_way_pattern`) plus `summary.json` (`total_agreements_ab`,

`total_all_three_agree`, etc.).

The system was implemented without any agent framework (no LangChain, CrewAI, or AutoGen). The orchestration logic lives in `orchestration.py`. This deliberate simplicity minimizes debugging surface area and keeps the pipeline transparent end to end.

3. Stock Selection and Rationale

Six stocks were selected to represent distinct market conditions, maximizing the probability of surfacing both agreement and disagreement:

Ticker	Market Condition	Expected Behavior
NVDA	Strong uptrend / momentum stock	Momentum: BUY (above MAs, strong trend). Contrarian: SELL or HOLD (near highs, potentially overbought). **Sharp disagreement expected.**
TSLA	Volatile, large price swings	Both agents should react to different aspects of the same volatility. Disagreement likely but direction unpredictable.
JNJ	Stable large-cap, low volatility	Both agents may converge on HOLD — no strong trend for Momentum to chase, no extreme positioning for Contrarian to exploit. **Agreement expected.**
INTC	Selected for decline-from-highs regime; on the run date captured a parabolic rally to ATH instead — producing an equally informative but different disagreement pattern (euphoria vs. trend vs. path risk)	Momentum: conflicted HOLD (trend says BUY but RSI screams overbought). Contrarian + Vol Averse: SELL. **Sharp disagreement confirmed, different axis than expected.**
GME	Meme / retail-attention volatility	Extreme swings and sentiment-driven moves; tests whether justifications stay data-grounded. Disagreement or noisy outcomes possible.
JPM	Large U.S. bank	Cyclical, rate-sensitive; contrasts with tech-heavy names. Mixed agreement/disagreement depending on trend vs. positioning.

Snapshot aligned to this run (2026-04-12)

One-line description of the **market data snapshot** each agent saw (from `outputs/*.json`); decisions in §4.

- **NVDA:** Uptrend vs highs — **three-way split: BUY / HOLD / SELL** (Momentum / Contrarian / Vol Averse); vol-focused agent rejects the tape as too turbulent (ATR ~2.75% of price).
- **TSLA:** Downtrend vs sold-off — **Momentum + Vol Averse SELL**, **Contrarian BUY** (classic trend vs fear; both sellers cite volatility / path risk).

- **JNJ:** Neutral tape — Momentum **HOLD**, Contrarian **HOLD**, Vol Averse **BUY** (low realized vol and shallow max drop vs. lack of trend/contrarian edge).
- **INTC:** Parabolic / ATH — Contrarian + Vol Averse **SELL**, Momentum **HOLD** (trend vs euphoria vs chaotic path).
- **GME:** Sideways — **unanimous HOLD** across all three (only name where **all_three_agree** in this run).
- **JPM:** Near highs — Contrarian **SELL**; Momentum **HOLD**, Vol Averse **HOLD** (2–1; vol agent pauses on choppy path).

4. Results by Stock

Run date (all files): 2026-04-12. Complete JSON (including `market_data_summary` and `strategy_c`) lives in `stocktrader/outputs/` — so results can be reviewed without re-running the code. This section keeps a **summary table** (all three strategies), **short excerpts** for four tickers, and **two verbatim excerpts** (full strategy + evaluator objects) for **TSLA** and **JNJ**. The **Appendix** summarizes decisions and key market data for **NVDA**, **INTC**, **GME**, and **JPM**.

4.1 Summary — all six stocks

Ticker	Momentum	Contrarian	Vol. Averse	A/B agree?	All 3 agree?
NVDA	BUY	HOLD	SELL	No	No
TSLA	SELL	BUY	SELL	No	No
JNJ	HOLD	HOLD	BUY	Yes	No
INTC	HOLD	SELL	SELL	No	No
GME	HOLD	HOLD	HOLD	Yes	Yes
JPM	HOLD	SELL	HOLD	No	No

Momentum vs Contrarian: 2 agreements / **4** disagreements (`total_agreements_ab` / `total_disagreements_ab` in `outputs/summary.json`). **Unanimous (all three): 1** (`total_all_three_agree`: **GME** only). The only **Momentum vs Contrarian** opposite-action pair (**SELL** vs **BUY**) is **TSLA**; **Volatility Averse** also **SELL** on TSLA (aligns with Momentum on direction, not on reasoning).

4.2 NVDA, INTC, GME, JPM — short excerpts (direct quotes from JSON)

NVDA (three-way split). Vol Averse: *"NVDA's 30-day volatility of 2.242% and 90-day volatility of 2.1607% both sit at elevated levels… The ATR as a percentage of price at 2.7541% means daily swings are averaging nearly 3% of the stock's value."* Full text: `outputs/NVDA.json`.

INTC (HOLD / SELL / SELL). Vol Averse: *"INTC's 30-day volatility of 4.61% and 90-day volatility of 4.64% are both alarmingly elevated… The ATR as a percentage of price stands at 5.07%."* Full text: `outputs/INTC.json`.

GME (unanimous HOLD). All three cite lack of a clean trigger; Vol Averse emphasizes ATR % and drawdown without a vol "all clear." Full text: `outputs/GME.json`.

JPM (2–1). Vol Averse **HOLD** with Momentum vs Contrarian **SELL**; path metrics (ATR, 90d vs 30d vol) justify pausing. Full text: `outputs/JPM.json`.

4.3 Direct excerpt — TSLA (strategies + evaluator)

Momentum Trader — SELL (confidence 8/10). *"TSLA is trading at $348.95, sitting -5.9% below its 20-day moving average and -11.5% below its 50-day moving average — a clear bearish positioning that signals the trend has reversed. The RSI of 41.97 is approaching oversold territory but hasn't bounced, confirming sustained selling pressure rather than a recovery setup. The 30-day price change of -14.59% and 90-day change of -18.88% paint a consistent downtrend with no sign of reversal, and negative days (16) outnumber positive days (14) over the last month. Even with increasing volume, that volume is confirming the downtrend rather than supporting a bullish case — the trend is clearly down and momentum traders must respect it."*

Value Contrarian — BUY (confidence 6/10). *"TSLA is sitting 28.77% below its 52-week high of $489.88, firmly in the territory where fear-driven selling creates contrarian opportunity. The 90-day max drawdown of -29.93% suggests meaningful capitulation has occurred, and the RSI of 41.97 is approaching oversold territory without yet triggering a full panic flush. The recent 5-day decline of -3.23% on top of an already beaten-down price suggests continued selling pressure, but this is precisely the uncomfortable entry point that tends to reward patient contrarians. However, the RSI has not yet breached the 35 threshold I prefer, and the stock remains well above its 52-week low of $227.50, so I temper my confidence — this is a measured buy, not an aggressive one."*

Volatility Averse — SELL (confidence 8/10). *"TSLA's 30-day volatility of 2.38% and 90-day volatility of 2.32% in daily returns are both elevated, indicating a persistently turbulent tape with no sign of calming. The ATR as a percentage of price stands at 4.42%, meaning the stock routinely swings more than 4% of its value in a single day — far too wide for a volatility-averse posture. The worst single-day drop over the last 90 trading days was -5.42%, and the max drawdown reached -29.93%, confirming that the path has been genuinely dangerous rather than merely drifting lower. These metrics collectively describe a chaotic, high-risk ride that violates my core requirement of orderly, controlled price action, and I would rather step aside than absorb further whipsaw risk."*

Evaluator. *"Momentum Trader and Volatility Averse both arrive at SELL but through entirely different lenses: Momentum anchors on the price trend itself — TSLA trading 5.9% below its 20-day MA, 11.5% below its 50-day MA, and posting -14.59% over 30 days with negative days (16) outnumbering positive (14) — while Volatility Averse focuses on the turbulence of the path, citing a 2.38% daily volatility, a 4.42% ATR-to-price ratio, and a worst single-day drop of -5.42% as conditions that make the ride itself unacceptable regardless of direction. Value Contrarian is the outlier, issuing a BUY at confidence 6/10, because it interprets the same price damage — a 28.77% decline from the 52-week high of $489.88 and a 90-day max drawdown of -29.93% — as evidence of fear-driven capitulation rather than a trend to follow. The Contrarian's hesitation is visible in its own framing: RSI at 41.97 has not yet breached the preferred 35 threshold, and the stock remains well above its 52-week low of $227.50, which is why confidence is tempered rather than aggressive. Momentum Trader reads the same RSI of 41.97 as confirmation of sustained selling pressure with no bounce, not as a setup for mean reversion. Volatility Averse is indifferent to whether the stock is cheap or trending — the 4.42% daily ATR and persistent turbulence alone disqualify it from a low-risk hold. The split reflects a fundamental philosophical divide: Contrarian weights distance from peak and potential*

capitulation, while Momentum and Volatility Averse both weight current conditions — one through directional signal, the other through path risk — and both conclude the environment demands an exit."

4.4 Direct excerpt — JNJ (strategies + evaluator)

Momentum Trader — HOLD (confidence 4/10). *"JNJ is trading at $238.46, sitting just below both the 20-day MA ($239.896) and 50-day MA ($240.2364), which is a red flag for a momentum trader — the price needs to reclaim these levels to confirm an uptrend. The 30-day price change is -2.06% and the recent 5-day change is -1.88%, signaling short-term downward pressure that contradicts the strong 90-day gain of +15.86%. Volume is decreasing and negative days (16) outnumber positive days (14) over the last 30 sessions, meaning there's no volume confirmation of a reversal. RSI at 56.86 is neutral and not a concern, but without price reclaiming the moving averages, I'm not pulling the trigger on a buy — I'll wait for a clearer breakout signal."*

Value Contrarian — HOLD (confidence 7/10). *"JNJ is only 4.06% below its 52-week high, which is far from the 20-30% drawdown threshold that would trigger a contrarian buy signal. The RSI of 56.86 sits comfortably in the neutral zone between 40 and 60, indicating neither overbought nor oversold conditions. The max drawdown over 90 days is a modest -5.35%, and the stock has actually surged 15.86% from its 90-day price — suggesting this is not a fear-driven capitulation but rather a stock near the top of its recent range. There is no compelling contrarian entry here, and chasing a stock this close to its 52-week high goes against my core discipline of buying fear, not complacency."*

Volatility Averse — BUY (confidence 7/10). *"JNJ's 30-day volatility of 0.9844% and 90-day volatility of 1.0479% are both modest, indicating a calm and orderly tape that suits a volatility-averse posture. The ATR as a percentage of price sits at just 1.7703%, confirming that daily swings are contained relative to the stock's price level. The worst single-day drop over the last 90 trading days was only -2.3115%, and the max drawdown of -5.3468% reflects a shallow stress path — neither figure signals dangerous tail risk. Taken together, these metrics paint a picture of a controlled, low-turbulence name that meets the criteria for adding exposure. The recent minor price softness is not a volatility concern and does not override the fundamentally smooth ride this stock has offered."*

Evaluator. *"Momentum and Contrarian both land on HOLD, but for entirely different reasons rooted in their respective frameworks. The Momentum Trader sees JNJ trading below both its 20-day MA ($239.896) and 50-day MA ($240.2364), with 16 negative days outnumbering 14 positive days over 30 sessions and a -2.06% 30-day decline — insufficient trend confirmation to act despite the strong 90-day gain of +15.86%. The Value Contrarian also holds, but because the stock is only 4.06% below its 52-week high and RSI sits at a neutral 56.86 — far from the fear-driven capitulation or 20-30% drawdown that would justify a contrarian entry. The Volatility Averse strategy diverges with a BUY, anchoring entirely on the smoothness of the price path: 30-day volatility of 0.9844%, ATR at just 1.7703% of price, and a worst single-day drop of only -2.3115% over 90 days all signal a low-turbulence environment that meets its threshold for adding exposure. Where Momentum sees a lack of upward confirmation and Contrarian sees a lack of downside dislocation, Volatility Averse interprets the same mild softness as a non-threatening, orderly pullback within a calm tape. The outlier's logic is path-focused rather than directional — it does not require trend strength or fear pricing, only the absence of dangerous volatility. This divergence illustrates how the same data point — modest recent price decline — is read as a warning flag by one lens, an irrelevant non-event by another, and a non-concern by the third."*

5. Patterns of Agreement and Disagreement

Where Strategies Agreed

Momentum vs Contrarian agreed on **JNJ** and **GME** (both **HOLD** on the Momentum vs Contrarian pair). **All three** agreed only on **GME** (unanimous HOLD).

JNJ (price $238.46, `outputs/JNJ.json`): Momentum and Contrarian both **HOLD** for the reasons in §4 — weak short-term structure vs no contrarian extreme. The **Volatility Averse** agent diverged with **BUY**, citing **low** 30d/90d realized volatility, **low ATR % of price**, and shallow worst-day / drawdown — a path-risk **all clear** that does not depend on trend or fear/greed framing.

GME (price $23.22, `outputs/GME.json`): All three **HOLD** — the snapshot's only **full unanimity**. Each lens finds a different reason not to act (mixed MAs, no capitulation, ATR/drawdown still uncomfortable).

Where Strategies Disagreed Most Sharply

The **clearest Momentum vs Contrarian fight** is **TSLA** (**SELL** vs **BUY**). **Volatility Averse** also **SELL**s, aligning with Momentum on **direction** while citing **ATR %**, **daily volatility**, and **worst single-day drop** — not trend labels.

NVDA is the run's **three-way split** (**BUY / HOLD / SELL**): trend vs "too rich" vs "tape too turbulent." **INTC** shows **Contrarian + Vol Averse** aligned on **SELL** (euphoria vs chaotic path) while Momentum **HOLD**s. **JPM** is a **2–1**: Contrarian **SELL** vs **HOLD**/**HOLD** — Vol Averse pauses on path risk rather than joining the contrarian exit.

What Drives the Divergence

Across these six runs, disagreement is largest when **the tape supports multiple honest stories at once**: a **directional** read (trend vs. counter-trend), a **positioning** read (cheap vs. rich vs. 52-week extremes), and—once the **Volatility Averse** agent is included—a **path-risk** read (smooth vs. turbulent; ATR and realized σ vs. tail drops). TSLA is the purest **two-strategy** example (downtrend vs. "already sold off"); adding the third agent shows the same numbers supporting **SELL** again for a **different** reason (unsafe ride). Agreement clusters when **no** philosophy sees a clean edge—most clearly **GME** (unanimous HOLD).

Cross-Stock Patterns (own analysis)

Two patterns emerged that the evaluator did not articulate. First, **RSI is the systematic divergence trigger** across the entire run. Every Momentum-vs-Contrarian disagreement involves an RSI reading that one agent interprets as momentum confirmation and the other as an overbought/oversold extreme: NVDA (68.17 — "sweet spot" vs. "approaching overbought"), TSLA (41.97 — "sustained selling pressure" vs. "approaching oversold opportunity"), INTC (80.35 — "overbought exhaustion" vs. "peak euphoria to sell"), JPM (73.69 — "nearing exhaustion" vs. "firmly overbought"). RSI is the single indicator that both strategies explicitly include in their frameworks but interpret through opposite lenses — making it the fulcrum of disagreement by design.

Second, the **Momentum Trader was far more conservative than expected**. It issued HOLD on 4 of 6 stocks, never once producing its "preferred" aggressive BUY on a clear trend stock like INTC. Even INTC — at its 52-week high, 20/30 positive days, increasing volume, price 29.5% above the 20-day MA — only

earned a conflicted HOLD at 5/10 confidence because RSI at 80.35 tripped the overbought safety valve. The prompt's RSI ceiling (75) effectively overrode every other momentum signal in the dataset. This suggests that including RSI as a Momentum constraint — while realistic — significantly narrows the window where the agent will act, biasing it toward caution in a way that makes it behaviorally closer to the Contrarian's patience than intended. A future iteration might relax the RSI ceiling or make it a "flag" rather than a hard gate.

This reflects the project's central point about **behavioral design**, not forecasting skill: agents disagree because they are instructed to **weight different columns of the same table**, and even internal prompt constraints (like RSI thresholds) shape behavior as much as the philosophical framing does.

6. Failure or Surprise Case

Primary case: Momentum Trader's RSI safety valve overrides its strongest BUY signal.

(1) What happened. On **INTC**, the Momentum Trader's own framework produced the strongest BUY setup in the entire dataset: the stock sat at its 52-week high ($62.38), price was 29.5% above the 20-day MA, 20 of the last 30 days were positive, volume was increasing, and the 90-day return was +53.8%. Every momentum signal pointed to BUY. Yet the agent issued **HOLD at 5/10 confidence** — its lowest-conviction call in the run — because RSI at 80.35 tripped the overbought threshold of 75 encoded in the prompt. The safety valve designed to prevent chasing exhausted trends also prevented the agent from acting on what would have been its single most decisive signal.

(2) Why it happened. The prompt's decision framework treats RSI > 75 as a hard gate rather than a weighted input. When RSI breaches 75, it effectively vetoes every other indicator — moving averages, volume, positive-day ratios, trend magnitude — regardless of how overwhelmingly bullish they are. This is a **prompt design tension**: the RSI ceiling makes the agent safer (it avoided what could be a blowoff top) but also makes it systematically unable to act on parabolic trends, which are exactly the moves a pure momentum philosophy should chase. The result is an agent that talks like a momentum trader but behaves like a cautious one.

(3) What I would change. Restructure the prompt so RSI > 75 triggers a **confidence discount** (e.g., cap confidence at 5–6) rather than a decision override. This would let the agent issue BUY with tempered conviction on parabolic setups, preserving the behavioral identity while still flagging exhaustion risk. Alternatively, raise the RSI ceiling to 80 or 85 for the Momentum Trader specifically, since trend-followers in practice tolerate higher RSI readings than value investors.

Secondary case: Evaluator language drifts toward "picking a winner." On **INTC** and **JPM**, the evaluator prose goes beyond explaining *why* the strategies diverged and describes the Value Contrarian as "more internally consistent" with its philosophy. This violates the evaluator's intended neutral role. The fix: add hard negatives to the evaluator prompt ("Do **not** say which strategy is more correct or better supported") and optionally post-process to strip comparative-judgment phrases.

Tertiary observation (persona leakage): On **JPM**, the Value Contrarian justification references **distance from the 20-day moving average** (`outputs/JPM.json`). The contrarian prompt is supposed to de-emphasize MA structure in favor of 52-week positioning and extremes — a small prompt-compliance slip useful for a future revision.

7. Reflection

If I had $10,000 and had to follow one strategy for the next month: I would choose the **Value Contrarian** because, across the six-stock run, its recommendations tracked the **mean-reversion story** in the data most transparently: it **sold** into clear **euphoria / overbought** combinations on **INTC** (at the 52-week high, RSI ~80) and **JPM** (RSI ~73.7, near highs), and it **bought TSLA** after a large drawdown from the 52-week high with RSI approaching oversold—exactly the "buy fear, sell greed" pattern the prompt encodes. I would not treat these as investment advice, but as a behavioral experiment the Contrarian's outputs were the easiest to connect to **specific** levels in the JSON. The **Momentum Trader** was more **conservative** than I expected: it **held** on **INTC** and **JPM** despite strong trends or hot RSIs—waiting for clearer trend confirmation or cooler RSI—which makes it **less** suitable for a single month if my goal were **maximally decisive** long/short calls, but **more** suitable if I wanted to avoid chasing parabolic moves.

A third hybrid strategy would combine both philosophies by using the Momentum Trader's framework as the primary decision-maker but applying the Value Contrarian's RSI and 52-week distance checks as a risk filter. Specifically, the hybrid would follow momentum signals for BUY/SELL decisions but override any BUY recommendation when RSI exceeds 75 or the stock is within 5% of its 52-week high (Contrarian's sell conditions), and override any SELL recommendation when RSI is below 30 or the stock has dropped more than 25% from its 52-week high (Contrarian's buy conditions). This captures the Momentum Trader's ability to identify strong trends while using the Contrarian's extreme-positioning checks to avoid buying at tops and selling at bottoms.

8. Third Strategy Agent (Volatility Averse)

I implemented a **third strategy agent**, **Volatility Averse** (behavioral focus: *survive first, avoid turbulence*; key inputs: standard deviation of daily returns, ATR, worst single-day drop over 90 days — all derived from **yfinance** OHLCV in `market_data.py`). The agent runs **in parallel** with Momentum and Value Contrarian on the **same** market data; outputs add `strategy_c` and `three_way_pattern` to each JSON file, and `summary.json` records **`total_all_three_agree`** (here: **1** of **6**, **GME** only) alongside the original **Momentum vs Contrarian** counts.

What this added: **three-way splits** (e.g. **NVDA**: BUY / HOLD / SELL) show that path-risk framing is **not** reducible to the two-way story — Vol Averse can reject a "good trend" or "calm contrarian hold" when ATR and realized volatility stay high. **TSLA** is instructive: Momentum and Vol Averse both **SELL**, but the second sells the **trend**, the third the **ride**. **JNJ** shows the opposite: Momentum and Contrarian **HOLD** while Vol Averse **BUY**s the **smooth** tape. The evaluator was extended to synthesize **three** outputs with explicit instructions **not** to crown a "winner." In short, the third agent makes **disagreement structure** richer: unanimous vs 2–1 vs three-way, and surfaces **why** each philosophy fires — not just whether two agents match.

Appendix: Decision Summary — NVDA, INTC, GME, JPM

Supplementary reference beyond the main report (Sections 1–8 above).

Complete JSON files for all six tickers are in `stocktrader/outputs/`. Verbatim excerpts for TSLA and JNJ appear in Sections 4.3–4.4. Below are the decision summaries and key market data for the remaining four

tickers; full justifications and evaluator analyses are in the repository JSON files.

Ticker	Price	RSI	30d Δ%	52w-High dist	Momentum	Contrarian	Vol. Averse
NVDA	$188.63	68.17	+2.03%	–8.88%	BUY (7)	HOLD (6)	SELL (7)
INTC	$62.38	80.35	+37.22%	0.00% (ATH)	HOLD (5)	SELL (9)	SELL (9)
GME	$23.22	56.14	–3.65%	–33.68%	HOLD (4)	HOLD (5)	HOLD (5)
JPM	$309.87	73.69	+1.74%	–6.92%	HOLD (5)	SELL (7)	HOLD (6)
